	What is pata structure 2
•	Data Structure is a way to store and organize
	data so that it can be used efficiently.
	As per name indicates itself that
	organizing the data in memory.
	The data structure is not any
	programming language like c, c++, Java etc.
	It is set or algorithms that we can use in any
	programming language to structure duta in memory
	The same and the same of the s
	Data structures
-	primitive data structure Non-Primitive Datastructu
_

-	Linear Data structure:-
	the arrangement of data in the
	sequential manner is known as linear data structur
	The data christing used for this auchase are

In this data structures, one element is connected to only one another element in a

Arrays, linked list, stacks and gueues.

linear form.

Non-linear data structure:-

when one element is connected

to the 'n' number of elements known as

hon-linear data structures.

Example: - trees and graphs.

In this case, elements are arranged

in a random manner.

Algorithms and Abstract Date types ex

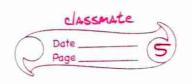

Algorithms

Abstract data types

set of rules

 $why \rightarrow$

TO structure the data in memory, 'n' number of algunthms are proposed, and all these algonthms are knowns as Abstract Data Types.

An Abstract Data Type tells what is to be done and data structure tells how is to be done?

ADT gives us the blueprint while data structure provides the implementation part.

What is Data &

value / collection of values.

for example :- student's name and its id are the data about student.

What is Record ?

Record can be defined as collection of various data items

example: - student entity; name, address, ourse and marks can be grouped together to term record.

What is file ?

File is a collection of various records

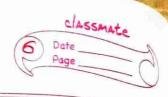

example: - if there are so employees in class,

then there will be so records in related

file where record rantains into at employee

What is Attribute and Entity ?

An entity represents class of certain objects it contains various attributes each attribute represents particular property of that entity.

As applications are getting amplaced and amount of data is increasing day by day, there may arrise following problems:

Processor speed:— As data is growing day by day to the billions of files per entity, processor may fail to deal with that amount of data.

Data Structure:— consider an inventory size of los items in store, if our application needs to search for a particular item, it needs to transverse be items every time, results in slowing down process multiple requests:— If thousands of users are searching data simultaneously on a webselver, then there are chances that to be failed to search during that process.

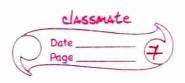

Structures are used. Data is organized to firm a data structure in a such way that all items are not required to be searched and require dates can be searched instructure.

Advantages of data Structure:
Efficiency: - If the choice of a data structure

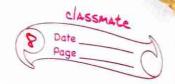

tor implementing a particular ADT is proper, it
makes program very etticient in terms of time and

space.

Reusability: - The data structure provides reusability means that multiple client programs can use the data structure.

	Abstraction: - The data structure specified by the
	ADI also provides level of abstraction. The client
	cannot see interval working of data structure, so
	it does not have to worry about implementation.

	Operations on data structure:
>	Traversing :- Every dota structure contains a
	set of duta elements. Traversing data struck
	means visiting each element of data structure
-	in order to perform some specific operation
	like searching or surting.
	Example: - If we need to calculate average
	or marks obtained by a student in a different
	subject, we need to traverse complete array
-	of marks and calculate total sum, then we will
	devide that sum by no of subjects ie & to find
	average.
	Full could be a further than the
)	Insertion : - Insertion can be defined as the
-	process or adding the elements to the duty.
W.	structure at any location.
\sim	If the size of data structure is n then we
	can only insert n-1 data elements to it.
>,	Deletion: - The process of removing an element
3 (The act structure is cultar deletion
-	we can delete an element from data structure
	at dig tarken location.
	If we try to delete an element from an
	empty data structure then underflow occurs.

searching: - The process of finding the location of an element within data structure is called searching. There are two algorithms to perform

searching, linear search and Binary search.

5). Sorting: - The process of all anging the data structure in a specific order is alled as sorting. There are many algorithms that can be used to perform sorting, for example, insertion sort, selection sort, bubble sort etc.

size m and n respectively, of similar type of elements, clubbed or joined to produce third list, list a of size (m+n), then this process is called merging.

DATA STRUCTURES AND ALGORITHM

What is Algorithm ?

An algorithm is a process or a set of rules required to perform culculations or some other problem—solving operations especially by a computer. It is not complete program or code; it is just a solution (logic) of a problem, which can be represented either as an informal aescription using a flowchart or pseudocode.

characteristics of an algorithm.

Input: - An algorithm has some input values. We can pass o or some input value to an algorithm.

output: - we will get I more output at end

unambiguity: - An algorithm should be unambigues which mouns that instruction in an algorithm should be clear and simple.

Finiteness: - An algorithm should have finiteness means limited number of instructions.

Effectiveness: - An algorithm should have finite as each instruction in an algorithm affects the overall process.

Approches in Algorithm :-

Brute force Algorithm: The general logic structure is applied to design an algorithm. It is also known as exhaustive search algorithm that searches all possible to provide required solution.

such alguntoms have two types :-

is optimizing 2), sacrificing finding all solutions of a As soon as the problem and then take best solution is found, then it will terminate stop.

If the best solution is known.

Divide and conquer: - This breaks down the
algorithm to solve the problem in different
methods. It allows you to break down problem
into different methods, and valid output is
produced for the valid input. This varied output is
passed to some other function.
passed to some other tunction.

Groody algorithm:— It is an algorithm paradigm that makes an optimal choice on each iteration with the hope of getting best solution. It is easy to implement and has faster execution time. But there are very rare cases in which it provides the optimal solution.

The major rategoines of algorithms are given below:

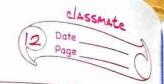

Sort: - Algorithm developed for surting the items
in a certain order.

search: - Algorithm developed for searching the "tems inside a data structure.

Delete: - Algorithm developed for deleting the existing element from the data structure.

Insert: - Algorithm developed for inserting an Ptem inside a data structure.

opaute: - Algurithm developed for updating the existing element inside a date structure.

Algorithm Analysis:

The algorithm can be analyzed in two levels in the algorithm, and second is after creating the algorithm.

There are two analysis of an algorithm.

Prior Analysis:

analysis of an algorithm which is done before implementing the algorithm.

Posterion Analysis :-

Here, pasterior analysis is a practical analysis analysis of an algorithm. The practical analysis is achieved by implementing algorithm using any programming language.

Algorithm complexity:-

The performance of the algorithm can be measured in two factors:

Time compexity:-

is the amount of time required to complete the execution. The time complexity of an algurithm is denoted by the big o notation.

Here big 0 notation is the asymptotic notation to represent time complexity. The time comprexity is mainly calculated by counting the number or steps to finish execution. sum = 0 ;

Il suppose we have to calculate the sum of n

for 1=1 70 n

sum = sum + i :

of n numbers.

return sum;

of the loop statement will be atleast n, and if value of n increases, then time complexity also increases.

complexity as it is maximum time taken for any given input size.

Space complexity:

An algorithm's space complexity is

the amount of space required to solve a problem

and produce an output similar to the time.

complexity, space complexity is also expressed in

big o notation.

Space comprexity = Auxiliary space + Input size.

	The following are the types of algorithms:
	Sourch Alamathan :-
	on each day, we search for something
	in our day to day life.
	similarly, with the rase of computer
	huge data is stored in a computer that
	whenever user asks for any data then the
	computer searches for that data in the
	memory and provides that data to the user.
	There are mainly two techniques available to
	search data in an array:
-	· Linear search
	· Binary search
-	the state of the s
+	=: 2017thag Algorithms:-
4	sorting aladrithms are used in
	elements in an array on a comp
+	is as ascending or dotto-
+	The comparison operator decides the new order

1	
1	

	A 1,190 A 1, 2
	Asymptotic Analysis:
	The time required by an algorithm comes
	under three types:
	Worst rase :- It defines the input for which
	the algorithm takes a huge time.
	a large of time for
	Average rase: - It takes average time for
	the program execution.
	a too exact for which
	Best rase: - It defines the input for which
	the algorithm takes the lowest time.
	1 hate Motor though the
	Asymptotic notations:
	used for calculating the running time complexity
	or an algorithm is given below:
	Big on notation (o):
	mis measures the performance of on
	algorithm by simply providing the order of
	growth of the function.
	This notation provides an upper bound
	on a function which ensures that function never
	gous faster than the upper bound.
-	gous taster Than the appropriate
-	† (CD)
-	P(n)
1	

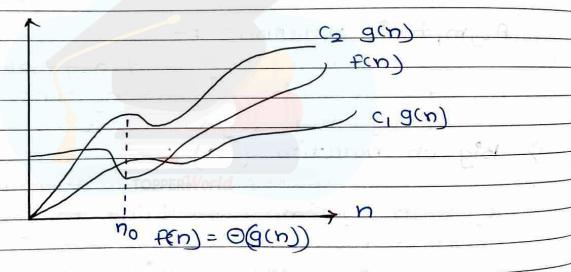

Example: - If find and gind are two functions defined for positive integer,

then find = 0 gind as find is big of of gind or find is an arrier of gind if there exists constants a and no such that:

find x c. gind for all n> ho.

2). Omega Motation (-2):
It basically describes best case
senario which is apposite to big a notation.

It is the formal way to represent lower bound
of an algorithm's running time.

Example: - let fin) and ginh be functions of humanore n is steps required to execute programs

Fin) = 0 gin)

The above andition is satisfied only if when: ci.g(n) < = f(n) < = (2.g(n))

2>.	omega Motation (-2)
	It basically describes best-case
	scenario which is opposite to big - o notation
	It is formal way to represent lower bound to
	an algorithm's running time. It measures the
	best amount of time an algorithm can possibly
	take to complete or best case time complexity.
	Example: - If f(n) and g(n) are two functions
	defined for positive integers,
	then f(n) = -2 g(n) as f(n) is omega of f(n)
	or fen) is on the order of g(n) if there exists
	constants c and no such that:
	Fin) > = c.g(n) for all n> no and c>o
	yans 1 or comes
	1 fcn)
	$C \cdot q(n)$
	World To OUOS
	> x auis
	no Ole
3>.	meta Notation (0)
<u>-/.</u>	The motal notation mainly describes
	average case scenarios. It represents realistic time complexity
	of an algorithm Big theta is mainly used when
	the value of worst-rase and pest rase is
	the value or morsi tase and bis issue is

same.

	La contract de la con
	Puinter:

Array :- Arrays are defined as collection of similar type of data items stored at contigous memory locations. Array is the simplest data structure where each data element can be randomly accessed by using its index number. Array declaration :int arr [10]; char arr [10]; float arr [5] Program without Array: #include < stdio.h> void main () int marks-1 = 56; marks - 2 = 78, marks - 3 = 89; float avg = (marks-1 + marks-2+ marks-3)/3; print (avg); Program by using Array:-#include < stdio.b> wid main int marks [3] = { 56,78,89}; inti float ava; for (i=0) i <3 ;i++)

avg = avg + marks [i];

printf (avg);

Complexity of Array operations:-

). Time comprexity:-

Algon+h m	Tube	THE COURSE OF
mgoniin)	Arrage case	worst rase
Access	0(1)	0(1)
search	0(n)	
insertion /	0(n)	0(n)
Deletion		0(n)
Service Di	O(n)	0(n)

e). Space compressity:
In Amay space compressity for worst

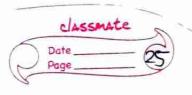

case is O(n)

Memory Allocation of the Array:-

Fach element in Array represented by indexing Indexing of array can be defined in three ways:

1. O (zero Based indexing):-

me first element of the array will be array.

	2.1 (one-based indexing):-
	The first element of away will be artij
	3. n(n-based inclexing):-
	The first element of array can reside at
	any random index number
	-:juborquitemub
	104
	A standard with a large to the property of
	arrso] arrs] arrs] arrs] arrs4]
	↑
	100 108
	Base address.
	Base address. (fig: int arr[5])
	Accessing elements of an Array:-
	To access any random element of an array
	we need the following information:
	1. Base address of the array
	2. size of an element in bytes.
	3. Which type of indexing, array follows.
	Address of any element of 1D array can be calculate
	Byte address of element A[i] = base address + size. * (first - index)
Example	In an array, A [-10 +2] Base adaress (BA)=999,

size of an element = 2 bytes, Find location of A[-i].

```
= 999 +18
                 = 1017.
        : 10 ration of A [-1] - 1017
        Passing array to the function :-
                The name of the array represents
        the starting address or the address of the
        first element of the array.
 Program: #include < stdio.hz
         int symmation (int[]);
         void main ()
          in+ arr[5] = {0,1,2,3,4};
          int sum = summation (arr);
          prints ("dod", sum);
        int summation (int arr[])
           in+ sum =0,1;
          for (1=0 31x5 31+4)
             Sum = Sum + arr [i];
          return sum ;
```

2D Array: - 2D array can be defined as an
array of arrays. The 2D array is organized as
matrices which can be represented as allection
of rows and coloumns.

How to declare en Array:
The syntan for declaration of two dimensions array is as follows:

int arr [max - rows][max - coloumns];

However, it produces the data structure which

Ī		0	la constitución de	2 Sac n-1	_
	0	a [o][o]	a[o][i]	a[a][2] a[o][p-]	_
1	1	a[][o]	alli	a[][2] a[][n-1]	
	2	a[2][0]	9(2)[]	a[2][2] a[2][n-1]	
	•				
	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	a[n-i][o]	a[n-1][1]	a[n-1][2] a[n-1][n-1]	
	h-1	المارا المال		C. C.	

a[n][n]

(Fig: a[n][n])

How to access data in 2D-array:
Due to fact that elements of 1D arrays

can be random accessed.

int x = a[i][i]

respectively.

Initializing 20 arrays:-

The syntan to declare and mitialize the 2D array is given as follows:

int arr [2] [2] = {0,1,2,3};

number of elements in 2D arrays

= number of rous * number of coloumns.

Mapping 2D array to 1D array:-

The size of a two dimensional array is equal to the multiplication or number of rows and number of colourns present in the array.

A 3x3 two dimensional array is a shown:

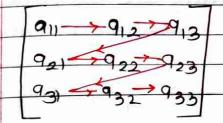

0 (0,0) (0,1) (0,2) coloumn indec 1 (1,0) (1,1) (1,2)

2 (2,0) (2,1) (2,2)

- row indec

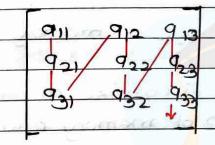

There are two main techniques of storing 2D

Raw major ordering:
In row major ordering, all the rows of 2D
army are stored into memory configuratly.

2. Column major ordering:

According to coloumn major ordering, all the coloumns of 2D array at stored into the memory configously.

Calculating address of random element of a 2D array:-

oumber of rows while n is number of accounting.

then address of an element a [i][i] is accounted as

Address (a [i][i])= B.A + (i*n+j)*size.
B.A -> Base Address

2). By coloumn major order :-

Address (a[i][i] = (j *m)+i) *size+8.A.

Linked 19st:
Why there is a need of linked 19st 2

The we declare an array of size 3. Ar we know that all the values of an array are stored in a continuus manner, so all three values of an array are stored in a stored in a sequential fashion.

Then, total memory space accupied by array wallow 3 f 4 = 12 bytes.

Drawbacks of using array:

- we cannot insert more than 3 elements in above example because only 3 spaces are allocated by 3 elements.

occur.

The array, we are providing fixed-size at compile time, due to which wastage of memory occurs. The solution to this problem is to use linked list

What is Linked list ?

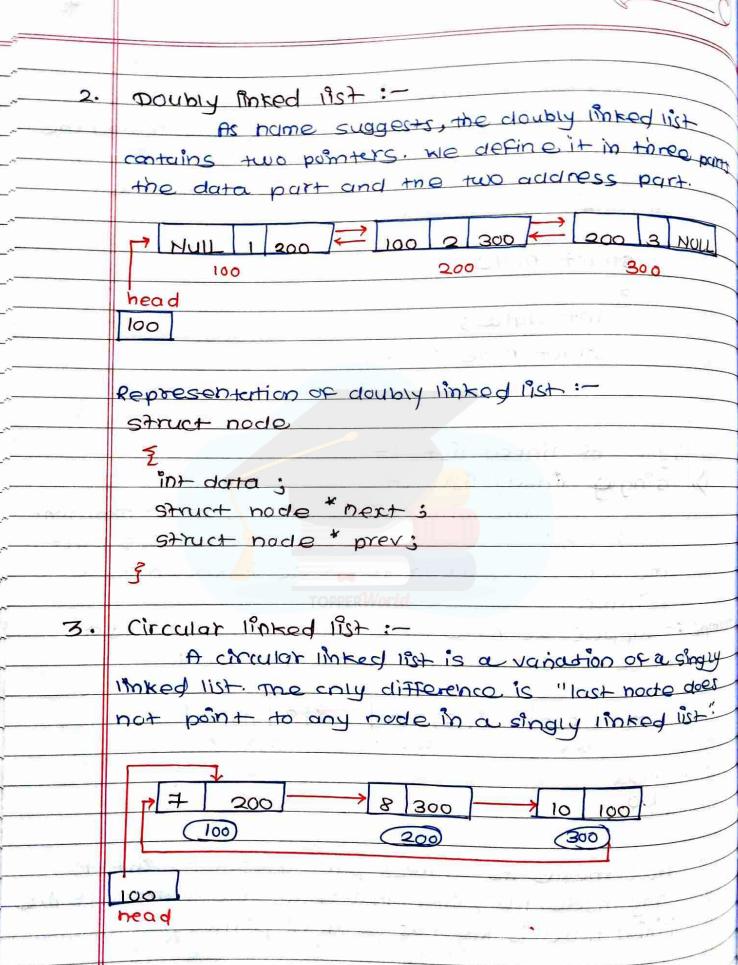

A linked list is also a collection of elements but the elements are not stored in a consecutive location. on linked list is a collection of the nodes in which one node is connected to another node and node consists of two parts is one is data part and second one is the address part.

Head

	empty or full. Different logic is implemented for
	different scenario's.
	Traversing: - In traversing, we simply visit out
	hode of the list at least once in order to perform
	some specific operation in it, for example, printing
	data part of each node present in the list.
-	searching: - In searching, we match each element
	of the list with the given element. If the element
	is found on any of the location of that element is
	returned ornerwise null is returned.
	- I tank to
	operations on doubly linked list:-
راا	Node creation :-
	struct node Toppelland
	And the state of t
	struct node previ
	int data;
	struct node "next;
	The part of the same of the same
,	Struct node "head;
	Just 1 to a 1 le 5 a
2	Insertion :-
	1). Insertion at beginning: - Adding the node into
	the linked list at beginning.
	1) Insertion at end: - Adding the node into the
	linked list to the end.

3). Deletion and Traversing: 1) Deletion at beginning: - Romoving the node the

beginning of the list

2) Deletion at end : - Removing the node framen of the list.

Traversing :- viviting each mode of the int at least once in order to perform some specific operation like searching, sorting, display etc

searching: - compaining each noise data with the item to be searched and return location of the item in the list if the item found else return hull

Skip list :-

What is a skip it P

A skip list is a probalistic data structure The skip list is used to store a linked list of elements or data with a linked list. In one single step, it skips serenal elements of the entire list which is why "It is known as skip list

Structure of skip list :-

skip list is built in two layers: The lowest layer and the top layer. The lowest layer of the skip ist is a common surred linked list, and the top layers of the skip list are the like an "expressing" where elements are skipped.

Stack: - A stack is a linear data structure that follows LIFO (Last-In-first-Out) principle stack has one end, whereas queue has two ends (front and rear).

A stack is a container in which insertion and deletion can be done from the end (one) known as the top of the stack.

A stack is an Abstract Data Type with a pre-clefined appartly, which means that it an store elements of limited size.

Operations on the stack :-

- is full overflow condition occurs.
- 2). Pop (): when we delete an element from stack, the operation is called as pop (). If stack is empty means no element exists in the stack, this state is known as an underflow state.
- 3). Peek (): It returns the element at a given position.
- 4). Count (): It teturns the total number of elements available in a stack.
- 5). change (): It changes the element at the given position.
- 6). display (): It points all the elements available in the stack.

PUSH Operation :-

check whethere the Stack is full.

If we try to insent element in a stack, and the Stack is full, then overflow condition occurs. when we instialled a stack, we set the value of top as -1 to eneck that stack is empty The elements will be inserted until we reach the max size of the stack top = top +1.

			30
		20	20
	10	10	10
emoty			Stackis

Fig: PUSH operation)

POP operation :-

Before deleting the element from the stack, we check whether the stack is empty.

If we try to delete the element from empty

stack, then underflow condition orcurs.

first access the element which is pointed by top. once the top operation is performed, top is

decremented by 1 ie top = top -1.

Queue :- A queue can be defined as ordered gueue: A queue un list which enquies insert operations to be personne atone and called REAR and delete operations to a - guere can be referred as to be first in first out list. Enqueue (Insertion) front Rear Dequeue (Deletion) Complexity of queue:-Average Sparce comp Acress search Deletion Insertion worst O(n) O(n) O(1) O(1) gueue O(n) Worst Access search Insertion Deletion Queue o(n) o(n) o(1)operations on queue:i). Enqueue: Enqueue is used to insent element at room end of the queve. It returns wid Dequeue :- dequeue operations performs the deletion from front end of queue. The deque operation can also be aesigned to void.

- 3). peek: Ins returns, element which is pointed by front pointer in the queue but does not delete.
 - 4), quoue overflow (is full): when queue is completely full, then it shows overflow condition.
- s) queue underflow (isempty): when there is no element in the queue then it throws underflow and ition.

Types of queue :-

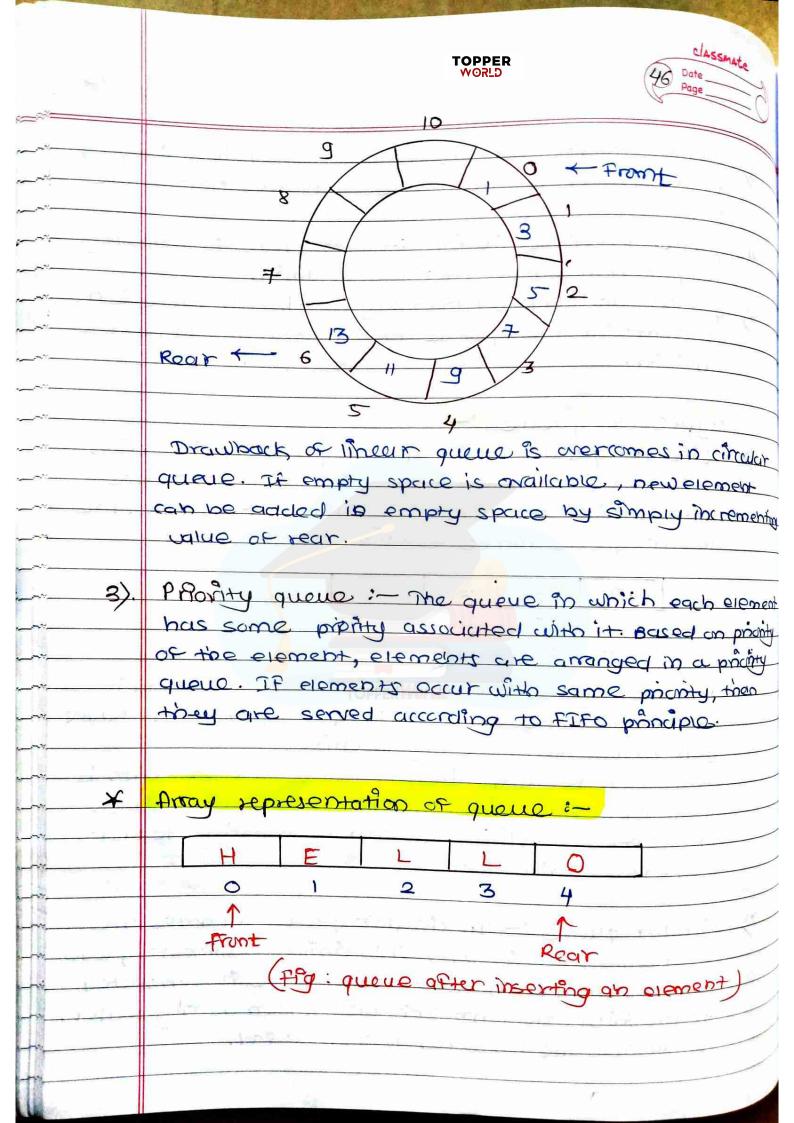

Linear queue: - In linear queue, an insertion takes place from one end while deletion occurs from another end. It strictly follows FIFO rule. The linear queue can be represented, as shown:

10 | 20 | 30 1 1 Front Roar

The elements are incerted from rear end, and it we insert more elements in queue, then rear values gets incremented on every insertion.

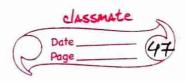

drawback is using linear queue is: insertion is done only from rear end. The linear queue inous the evertlow condition as rear is pointing to last element of the queue.

2). Circular quoue: - In circular queue, all nodes are represented as circular. It is similar to linear queue except that last element of the queue is connected to the first element. It is also known as ring buffer. as all ends are connected to applicar end.

Thee :- We read data smuture, like an aray maked list, stack and queue in which all element are arranged in a sequential manner.

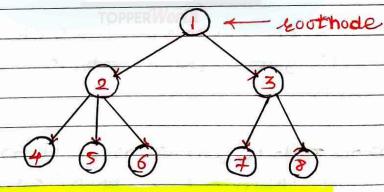

A tree is one of the cluter structures that

represents hierarchical data.

defination: — A mee is a data structure defined as collection of objects or entities known as nodes that are isneed together to represent or simulate hierarch A tree is a non-linear data structure because it does not store in a sequential manner. It is a hierarch structure as elements in troo one arranged in multiple levels.

In the data structure topment node is called as root node. Each node contains some data of duta can be of any type.

Each node antains some data & little or reference of other nodes that can be called children.

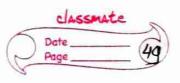

some pasic terms of thee :-

link: - each node is labeled with some number each array shown in fig is known as link between two nodes.

Root: - The bot node is top most node in the hierarchy. root node is one that doesn't have any purent. If node is directly linked to some other

	using arrays. It is used to implement priority queller

Types of Free data structure:

General Type: - In a general troe, a node an have either o or maximum in number of nodes.

There is no restrictions imposed on the degree of node (number of nodes that a node can contain)

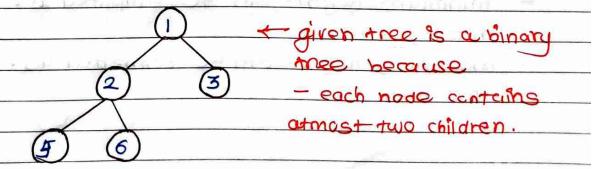

The topmost node in a general tree is known as root node. The children of parent node are known as subtroe.

mere on be n number of subtrees in general tree. In general tree, subtrees are unordered as nodes in subtree cannot be ordered.

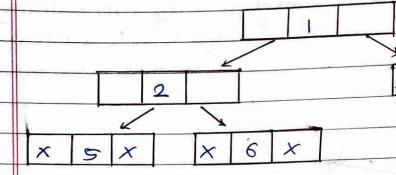

these edges are connected to nodes known as child nodes. The nodes that have same parent are known as siblings.

2). Binary Tree: - Binary tree means that the node can have marihum two children.

3

In above thee, node I contains two pointers in above thee node I contains two pointers in left and right pointer pointing to left and right node respectively.

menodes 3,5 and 6 are leaf nodes, so all these nodes contains NULL pointer on both left and right parts.

Properties of Binary tree :-

- At each level of is the manumum number ad nodes is 2'.
- The height of tree is longest puth from rout node to leaf node. In general, maximum number of nodes possible at height is (2°+21+22+...2")

 The minimum number of nodes possible at height h
- is equal to htl.

 If number of nodes is minimum, then height of
 the would be maximum.
- minimum height can be amputed as:

 h = leg 2 (n+1)-1
- modiminant height can be computed as:

=	
	Types of Binary mee:
	full propor strict Bingry tree :-

4). ALL Tree :- ALL Thee is invented by GM Adelson
-velsky and FM Landis in 1962. The tree is
named as ALL in honour of its inventors.

AND tree is dofined as height balanced binary search tree in which each node is associated with a balance factor which is calculated by subtracting the neight of its R. subtree from its left subtree.

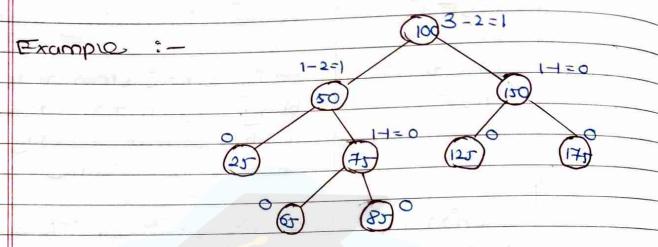

Balance factor (K) = height (left (K)) - height (right (K))

If balance factor of any node is 1, it means that left sub-tree is one level higher than right subtree.

- If balance factor of any node is 0, it magns that left sub-tree and right sub-tree contain equal height.

TF bulance factor of any node is I, it means that tett sub-tree is one level lower than right subtree

Here we see that, balance factor associated with each node is between -1 and +1.

-: It is an example of AVL treo.

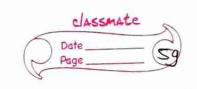

comprouty:- TOPPER WAR

Algoirthm	Average rase	Worst rase
space	o(n)	O(n)
search Insert	0(logn) 0(logn)	$O(\log n)$ $O(\log n)$
Delete	0 (log n)	o (log n).

why AVL Tree P -> AVL tree controls height of binary search tree by not letting it to be skelled me time taken by all operations in BST is O(h).

However it will be extended to O(n) If BST became

TOPPER WORLD

skewed (worst case). By limiting this height to log in, AVL tree imposes an upper bound on each operation to be O(logn), where n is number of nodes.

Operations on AVL, ee:-

1	ST. NO	operation	Description.
	<i>y</i> ·	Insertion	Insertion is performed in
			in BST. However, it may
		Line Later Control and	lead to violation in the AVL tree property and
		AL STATE	balancing and tree can

	27.	TOPPER Wanted	utily performed as BST Itan be also distrutt
		1	balance of theo, so
			various types of rotations are used to rebulance
			treo.

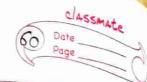

AVL Rotations:

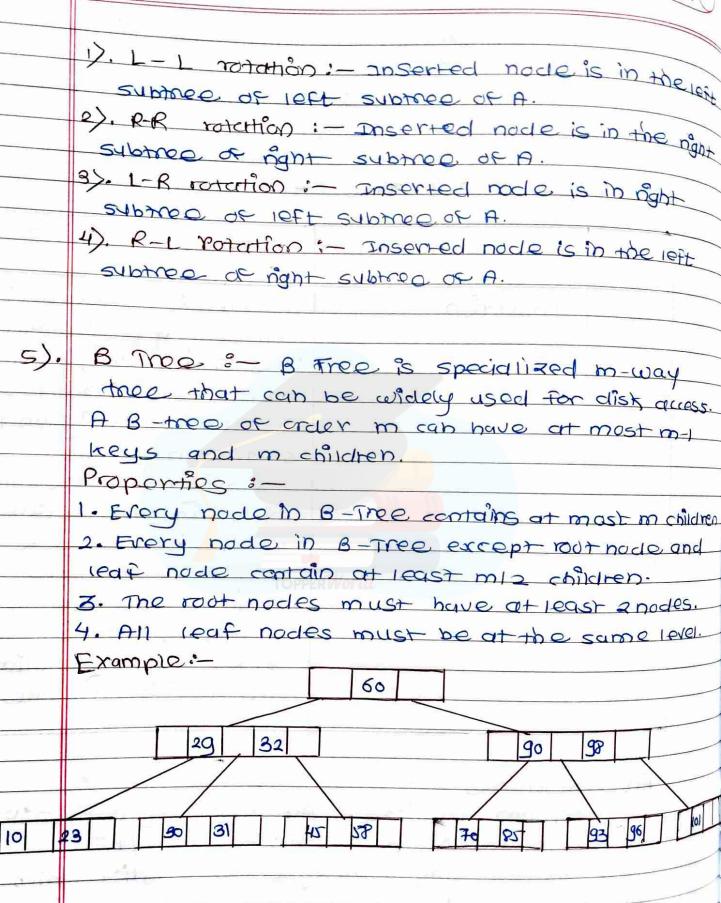

We perform rotations in AVL tree only in case if

Balance factor is other than -1, a and 1.

There are Basically four types of rotations which

are as follows:

0	perations	5-
_		

searching :- The searching in Btree is similar to searching in Binary tree for example, we search for an item 4g in following B Tree. The process will be:

(3. compare item 4g with root node 78. sinco 49×78 hence, more its left sub-tree.

- 2) since, 40×49×56, traverse right subtree of 40.
- 3. 49 >45, more to right compare 49.
- a match found, return.

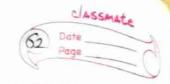

searching in B tree depends upon height of the tree. The search algunithm takes octagn) time to search any element in B tree.

- Inserting: Insertion are done at leaf node level.

 The following algorithm needs to be followed in order to insert an item into B tree.
 - (). Traverse B tree in order to find appropriate. leaf node at which node can be inserted.
 - 2). It leaf node centains less than m-1 keys then ment element in increasing order.
 - 3. FISE, if leaf node contains my keys, then following steps:
 - Insert new element in increasing order of
 - split node into two nodes at median.
 - Push median element up to its parent node.
 - If parent node also contain m-1 number of keys, then split it too by steps.

Application of B tree:-

B tree is used to inder data and provides fast access to actual data stored on disks since, the

stored on a disk is a very time consuming process.

searching an un-indexed and unsurted actually containing n key values needs o(n) running time.

6). B + Tree !-

efficient insertion, deletion and search operations.

The 1807 nodes of B+ tree are 1811 ked together in form of the singly linked list tumuko search queries more efficient.

Advantages of B+ tree :-

- y. Records can be fetched in equal number of disk accesses.
- 2) Height of thee remains bullanced and less as compute to 8 thee.
- 3) we can access date Stored in B+ theo soquentially as well as directly.

4) keys are used for indering.

Graph :-

A graph can be defined as group of vertices and edges that are used to connect these vertices.

Defination:

set G(V, E) where V(G) represents set of edges:

CN 1987				0
which are	11500	10	connect these	Mortices
WITH CHAN	U U		COLLINE TO THE SEC	VELITE

Directed and Undirected Graph :-

A graph can be directed or undirected.
However, in an undirected graph, edges are not associated with directions with them.

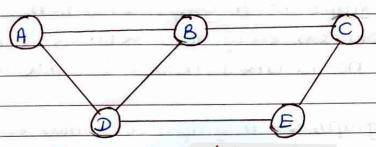

Fig: Undirected graph

As above figure edges are not attached with any of the affections.

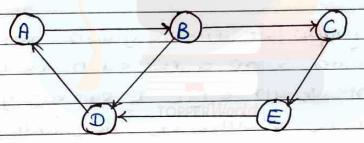

Fig: directed graph.

In above figure, directed graph edges form an ordered pair.

Franchiology:

1). Path: A path can be defined as sequence of nodes

that are followed in order to reach some terminal

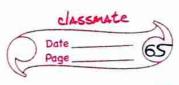

node v from initial mode v.

2). closed path: - A path will be called as closed if initial node is same as terminal node. Yo = VN

TOPPER WORLD

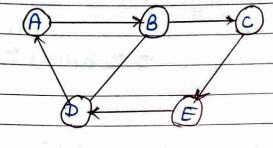

3).	Simple path: If all nodes of graph are distinct with an exception $V = V_N$, then such path p is called as closed simple path.
4).	(ycle: - A cycle is a path which has no repeated edges or vertices except first and last vertices
5].	connected graph: - A graph in which some puth exists between every two vertices (u, v) in v. There are no isolated nodes in connected graph.
6).	comprete graph: - A graph in which every node is connected with all owner nodes. A complete graph contain n(n-1) edges where n is number of hours In graph.
7).	Weighted graph: In this graph each node is assigned with some data such as length cruidth The weight of an edge e can be given as well which must be positive (+) value indicating costor traversing edge.
8).	siagraph: -A diagraph is directed graph in which each edge is associated with some direction and traversing can be done only in specified direction.
g ,	Loop: - An edge that is associated with the similar end points as be called as loop.
107.	Adjacent Nodes: If two nodes u and v are connected via an edge e, then nodes u and v

	are called as neighbours or adjacent nades.
<u>i</u>).	pegree of a Node: - A degree of a node is a number of edges that are connected with that node. A node with degree 0 is alled isolated.
-	Graph Representation:
	we samply makin, technique which is to be used to in order to stone some graph into the computers memory.
).	sequential representation: - In this we use adjaracing matrix to store nonpoing represented by vortices and edges. A graph having a vertices, will
	have a dimension nxn. An entry Mij in adjacency matrix representation
	of an most undirected graph of will be lift there exists an edge between v; and vj. An undirected graph and its adjacency matrix representation is shown in following:

TOPPER WORLD

An adjucency list is maintained for each node present in graph which stones node value and a pointer to next adjucent node to respective node.

In directed graph, sum or lengths of all the adjuncy lists is equal to the number of eages present in the graph.

Graph Traversal Algorithm:-

by using which, we can traverse all the vertices of the graph. Traversing means examining all nodes and retices of graph. There are two standard methods by using which, we can traverse graphs.

- · Breadth first search
- · Depth first search

Breadth first search (BFS) algorithm:—

Breadth first search is a graph traversal algorithm that setarts traversing graph from root node and explorer all the neighbouring nodes.

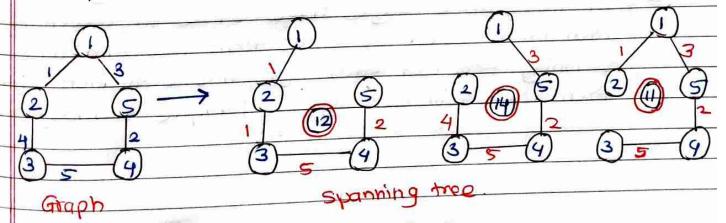

Then, it selects nearest node and explore all unexplored nodes. The algorithm follows same process for each of nearest node until it finds goal.

	Algorithm:

	Spanning Tree: The have a graph ontaining of rentices and
3	It we have a graph emany
	F edges, then graph can be represented as:
	G(V, E). If we create spanning tree From above
	graph, then spanning tree would have some number

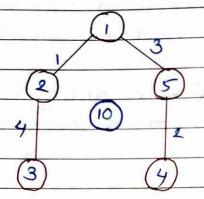

of vertices as the graph no or eagely graph)edges (spanning tree) =

Example:

Minimum Spanning Trees :The minimum spanning tree is a tree whose sum of edge weights is minimum.

In above tree, total edge weight is less than above spanning trees, therefore a minimum spanning tree is a tree which is having abedge weight is 10.

Properties of Spanning tree :-

spanning tree.

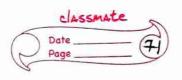

All possible spanning trees that can be created from given graph of would have some number of vertices in given graph minus 1.

spanning tree closs not contain any cycle, let's

understand this property through an example.

- spanning tree cannot be disconnected If we remove one more edge from any of above spanning trees as

then there will be only one I unique spanning tree

Applications of spanning tree:

Building a network: - suppose there are many routers in network connected to each other, so there might be a possibility that it forms a loop.

Custering: - clustering means that grouping set of objects in such way that similar objects belong to sume group than to different group. our goal is to divide the nobjects into k groups such that

distance between different groups gots manimised

Searching :-

searching is a process of finding some particular element in Jist. If the element is present in the list, then process is called successful and process returns location of that element, otherwise search is called un successful.

There are two methods widely used as below:

- · Unear search
- · Binary search

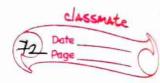

1). Theor search :-

inear search is a simplest sequential search search algorithm and often ralled sequential search. In this type of searching, we shoply traverse the list completely and match each element of list with item whose location is to be found.

Incar search is mostly used to search an

linear sparch is mostly used to search unordered list in which items are not sorted.

The algorithm is given as follows:

	Algorithm:
	LINEAR - SEARCH (A,N, VAL).
	STOP 1:- [INITIALIZE] SET POS = -1
	STED 2 :- [INTITALIZE] SET I =
	step 3: - Report step 4 while I x = N
	Step 4:- IF A[I] = VAL
	SET POS =1
	PRINT POS
	Go to step 6
	[FND OF IF]
	SETI=I+1
-	(FND OF LOOP).
4	Step 5:- IF POS =-1
	PRINT "VALUE IS NOT PRESENT IN ARRAY"
-	[FND OF JF].
-	step 6: - ExIT.

```
int 9 [10] = { 10, 23, 40, 1, 2, 0, 14, 13, 50, 9}3
     int item, i, flag;
      printf ("In forter Item which is to be secreted In");
      scanf ("god", item);
      for (1=0;1 <10;1++)
       { (a[i] = = item)
        break;
       if (flag 1 =0)
       printf ("In item found at location old In", Flag);
       else
       prints ("In Item not found In");
Output: - Enter Hern which is to be searched
        Item not found
       Enter Item which is to be searched
        23
```

Item found at location 2

2). Binary Search:

Binary search is a search technique which works on etticiently on sorted lists. Here in ander to search an element into some list by using binary search technique, we must ensure that list is sorted.

Binary search follows divide and conquer approach in which, list is divided into two halves and item is compared with middle element or list.

Binary search Algorithm:

Binary search (A, lower-bound, upper-bound, VAL)

Step 1:- [INITIALIZE] SET BEG = lower-bound

FND = upper-bound, pos = -1.

step 2: - Repeat steps 3 and 4 while BEGY= END

Step 3:-SET MID = (BEG+END)/2

SET RUS = MID

SET RUS = MID

PRINT PUS GO tO SEP 6

ELGE IF A[MID] > VAL

SET END = MID - 1

FLGE SET BEG = MID + 1

Step 5:- IF POS = -)

PRINT "VALUE IS NOT PRESENT IN ARRAY"

Step 6:- EXIT.

Bucket Sort Algorithm &-

The data items in the bucket surt are distributed in Ferm of buckets.

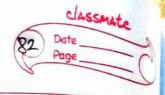

Bucket sort is a sorting algorithm that separtes elements into multiple groups said to be buckets. Elements in bucket sort are first uniformly divided into groups called buckets, and then they are sorted by any other sorting algorithm. After that, elements are gathered in sured mather.

Advantages of bucket soft are :-

- · Bucket surt reduces no or comparisons
- · It is asymptotically fast because of uniform distribution of elements.

limitations of bucket sort are:

- . It may or may not be a stable sorting algorithm
- · It is not useful if we have a large array box it increases the cost.
- . It is not an in-place surting algorithm, because more some extra space is required to surt the buckets.

	The best and average-case complexity
	of bucket soft is o (n+k), worst-case
	complexity or bucket sort is o(n2), where nis
	number of îtems.
	Bucket sort is commonly used:
	with floating - point values.
	when input is distributed uniforming over a
	range.

1 10 23 26 28 43 48.

Insertion sort Algorithm:

Insertion sort works similar to the sorting or playing cards in hands. It is assumed

that the first card. The idea behind the insertion surt is that first make trake one element, iterate it through sorted array. complexity of insertion out in the average case and worst ruse is

o(n2), where n is number of items

Theretion sort is less efficient than the other sorting algorithms like heap sort, quits surt and merge sort etc.

moention sort has various advantages such as:
simple implementation.

- · Efficient for small data sets.
- Adaptive i.e it is appropriate for data sets that are already substantially sorted.

```

A STRUCTURES INTERVIEW GUESTIONS

et What is data structure ? A data structure is a way of organizing data that considers not only items stored, but also their relationship to each other. p.2. List out the areas in which data structure are applied extensively ? · compiler design , operating system, · database system, · statistical analysis, · numerical analysis, · artificial intelligence 93. What are major data structures used in following areas Rabins, network data model and Hierarchical data model. > Rabons = array (array of structures). network data model = graph. Hierarchical dater model = tree. 94. If you are using clanguage to implement the heterogeneous 19nked 19st, what pointer type will you use ? The neterogeneous linked list contains different data types in its nodes and we need a link, pointer to connect thom. It is not possible to use ordinary pointer for this, so we go for wid pointer

void pointer is capable of steming pointer to any

	type as it is a generic pointer type.
₁	Je wo man we generic point
0.0.	minimum number of queues needed to
) -	implement the priority queue?
	two one queue is used for actual storing
	or data and another for sturing priorities
9.6.	What is data structure used to perform
	occursion ?
	stack because of its LIFO (Last IN first out)
	property it remembers its caller'
1 5	
9.7.	
	anthmatic expressions using prefix & postfix forms?
	Polish and Reverse polish notations.
	LIE LIBRO TIMENTE DELLA PARTICIONALE PARTICIONA
9.8.	convert expression ((q+b) c-(d-e) (f+g)) to
	equivalent prefile and postfix notations.
\rightarrow	prefix notation: - "+abc"-de+fg
	postfix notation: ab+c *de-fg+ 1-
-	
9.9.	what are methods available in string sequential
F-ALT P	Files ? 1. straight merging,
\rightarrow	2. natural merging,
-u7.5-	3. polyphase surt,
	4. distribution of initial runs.
- 6.	
Q.10·	Whether linked list is a linear or non-linear
	data structure?

110

	According to acress strategies linked list is a
	according to stemas intend list is a
	non limar one.
0.11.	define doubly linked list.
_ _	It is collection of data elements called podes.
	whore each nade is divided into three parts:
	· an info field that contains information stored in
	the node.
	· left field that contain pointer to node on left
	side.
	· Right field that contain pointer to node on right
	side.
	Called the state of the state o
9.12.	What are the Issues that bampers efficiency in
	sorting a file ?
\rightarrow	. readty of times redrived ph beorgenmen in aging
	a particular surting program.
	· amount of machine time noce scary for runining
	the particular program.
	· amount of space necessary for particular pan.
	· object cinented analysis and design.
9.13.	calculate efficiency of soquential search ?
\	The number of campainsons depends on where
\	the record with argument key appears in table
	· It it appears at first position then one comparison.
	· It it appears at last position then n comparison.
	· average = n+1. comparisons.
	2

	· number of comparisons in any case is out
9.14.	Is any implicit arguments are passed to a
->	function when it is called & yes, there is a set of implicit arguments that contain information necessary for function
F 200	to execute and return correctly, one of them is
	return address which is stored within the
	Function's data area, at time, of teturning to
	calling program address is retrived and function
There are	branches to that location.
8.15.	Parantheirs is never required in postfix or
	prefix expressions ? Why
\rightarrow	parenthesis is not required because order of the operators in postfix prefix expressions
	determines actual order of operations in
	evaluating expression.
1-2-	TOPPERWorld
9.16.	List out few of applications of the duta
	The manipulation of anthmatic expression,
	symbol table construction of syntax analysis.
9.17.	List out few of applications that make use of
	muttilinked structures?
	sparse matrix, Index generation.
9-18.	what is type of the algorithm used in solving g queens problem ?
	116

40

7	backtracking.
9.19.	In an AVL Tree, at what condition balancing is
)	
<i>></i>	If pivotal value, or height factor is greater
	than I or less than -1.
	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
9.20	In Robons, what is the efficient data structure
	in internal storage representation.
->	b+ tree. because bt tree, all the data is
	stored in only in leaf hodes, that makes searching
	easier this corresponds to records that small
	be stored in legf nodes.
	And the last of the state of th
9.21.	what is difference between array and a stack ?
\rightarrow	Stack follows LIFO. thus the item that is first
	entered would be last to be removed.
	In the array, items can be entered or removed
	by in any order basically, each member across
	is done using index no strict ander is to be
	followed here to remove a particular element.
	The second secon
.22.	How to check whether a linked list is circular?
\rightarrow	create two pointers, each set to start or list.
	update each as follows:
	unile (pointer 1)
	3
	pointer 1 = pointer 1-> next;

pointer 2 = pointer 2 -> next;

if (printer 2) pointer 22 pointer 2-7 nout;

73.5	WORLD
_ 4	if (pointer 1 == pointer 2)
	3
	print ("circularn");
= ->	3
	J.
9.23.	xhat is a node class?
	A node classis class that, relies on the
-	hase for service and implementation,
	provides a wider interface to users than its
	base class, relies primarily on virtual functions
	in its public interface depends on all its direct and indirect base class.
	arra trancop pase class.
9.24.	when can you tell that a momony leak will
	occur ?
\rightarrow	a memory least occurs when a program loses
	the ability to free a block of dynamically allocated method.
	anotared memory.
9.25.	what are types of collision resolution techniques
المستناسين	and methods used in each of the type o
	open addressing (closed hashing) methods used
7.25	include: overflow block closed addressing copen
	hashing) methods used include: linked list, binaryther
Q-26.	Which is simplest tile structure? (sequential,
	more (minor).
\rightarrow	sequential is the simplest file structure.
_	

-65

9.24	what are the notations, used in evaluation of arithmatic expression, using prefix and postfix forms? Polish and poverse polish notations.
928	Ist out few of applications of theo data structure? The manipulation of anthmatic expressions, symbol table construction and syndax analysis.
g.2g.	difference between rather and matter? matter allocate in bytes. calloc : allocate in times in bytes initialized to 0.
9.30· →	which file contains the definition of member function defination of member function for the linked list class are contained in linked list cpp file.
9·3I.	How is the front of the queue calculated? The front of the queue is calculated by front = (front +1) 90 sizes.
9.32.	why is the Isempty () member method called? the isempty () member method is called within the dequeue process to determine if there is an item in dequeue to be removed is isempty () is called to decide whether queue has at least on e element. This method is called by dequeue () method before returning front element.
9.33.	Which process places date at back of queue?

	enque is a process that places data at
	back of the queue.
	sacri of the quant
0 2/1	1.1h att % attents 0
9.39.	What is queue &
\rightarrow	A queue is sequential organization of data a
	queue is a first in first out type o'F date
	structure an element is inserted at last position
	and an element is always taken out from
	first position.
	\$ 200 me 1 x 8 2 mm 1 2 mm (2 200 (2 2 10 mm) 2 mm)
9.35.	What does is empty () member method determine
->	
11	element. this method is called by pop () before
9-12.	retrieving and returning top element.
9.86.	What method ternoves value from top of a
	Stack 8
	The pop() member method removes value
	from top of a stack, which is then returned
	by the pop () member method to statement
	that calls popel member method.
7	C. L. C. Large C. Liller and C. Lange C. Company
0.37	what method is used to place a value
ر.	onto the top of a stack ?
	push () method, push is the direction that
	date is being added to stack, push () member
	method places a value anto the top of a
	Stack.
0.28	How do you assign an address to an element
7. 30	Jun and address to an element

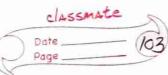

shift.

	or a pointer array?
*	de can assign a memory address to an element of a pointer array by using the address operator, which is ampersand (f), in an assignment state -ment such as premployee [o] = & projects [2];
g.39.	How many parts are there in a declaration
<u></u>	There are two main parts, variable, identifier & data type and third type is optional which is type qualifier like signed/unsigned.
940·	ist some or the static data structures in c? some or the static data structures in c are arrays, pointers, structures etc.
→	define dynamic data structure? A data structure formed when humber of data items are not known in advance is known as dynamic data structure or variable size data. structure.
g.42. →	lists, stack, queues, trees etc.
д. 1 3.	define finear dater structure. linear dater structures are datar structures having a linear relationship between its adjacent elements. eg: linked list.

9.44.	define non-linear data structures. Hon linear data structure are the data Structures are data structure that don't have a linear relationship between its adjacent elements but have a hierarchical relationship between the elements. eg: trees and graphs.
J.45.	state the different types of linked lists e The different types of linked list include singly inked list, doubly linked list and circular linked list:
9-46.	List the basic operations carried out in a linked list ? • creation of a list. • deletion of a node. • modification of a node. • traversal of a node.
9-47.	stack is an ordered collection of an elements in which insertion and delections are restricted to one end. The end from which elements are added and or removed is referred as top or stack.
9.48.	List out the basic operations that can be performed on a stack. • push operation.

TOPPER WORLD

	The second secon
	· pop operation
	· peek operation
	· empty check
	· fully occupied check.
	2 .085)00
.49.	State the different ways or representing expression
<i>></i>	· Infix natation.
	· prefix notation
	· postfix rotation.
